

## Normal Patient ECG Visualization

Provided 12 lead ECG data.

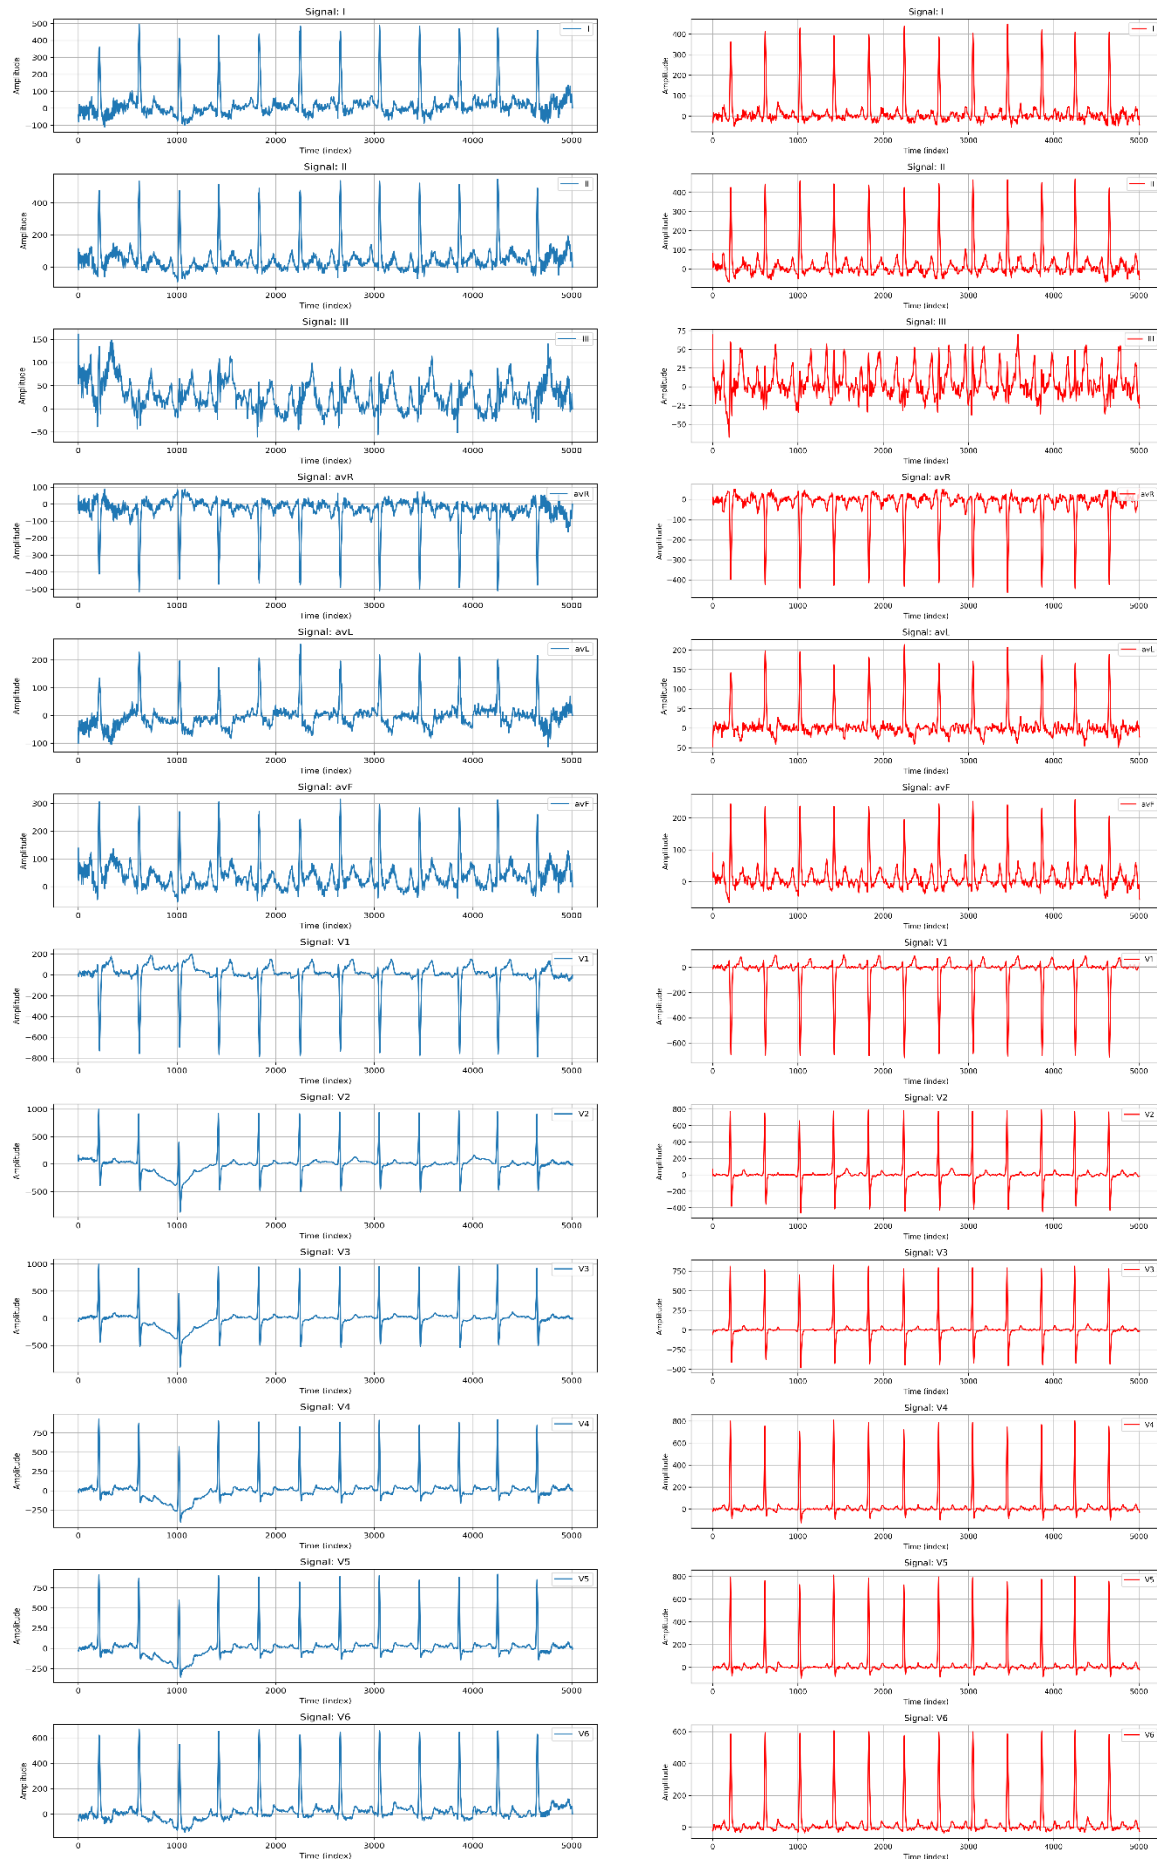

Patient name/ ID : 42998\_Kassa Ishwar. Left side has raw plot V/S Right side which has the cleaned signal

## Left ventricular dysfunction patient

Patient ID : 38963-7324\_Khilare Mahesh. Left side raw plot V/S right side cleaned signal

The data provided has different kinds of noise and anomalies present. The three main components of noise are the baseline drift, powerline (high frequency noise including but not limited to EMG noise) and outliers as well.

While the neurokit2 library does possess a huge arsenal for ECG analysis it was sometimes incapable of removing baseline drift heavily corrupted signals.

We have tried to implement a morphological filter based on different research articles. This method has yielded consistent visually sound ECG signals as compared to only using neurokit2's preprocessing tools.

High frequency noisy has been removed by the signal filter method provided by the Neurokit2 library.

To remove outliers we created a novel method of using a sliding window over the entire range of the signal to store the minimum and maximum values in the window. We then find out the steady state region and use it for our analysis.

There may also be Premature Ventricular Contraction artifacts in the ECG signal. We can decide how we wish to deal with that issue as it is not a conventional noise but a different contraction.

## Visualization of Normal and LV Dysfunction Superimposed signals

In the following diagrams we have plotted the average heart beat for a healthy and ailing patient for all 12 leads. This might allow us to see any early connection to L V dysfunction, or that we need more data to comment.

We have had to use Z- score normalization for the two plots to get a better understanding of the shape of the heart beats

The 2 patients plotted are the same as above. (NOTE there is no particular order in which way the graphs have been attached below)
